## Data Mining

## Lecture 15:

## Center-based Clustering

## K-means Clustering

- Partitional clustering approach
- Each cluster is associated with a centroid (center point)
- Each point is assigned to the cluster with the closest centroid
- Number of clusters, K, must be specified
- The basic algorithm is very simple

1: Select $K$ points as the initial centroids.
2: repeat
3: Form $K$ clusters by assigning all points to the closest centroid.
4: Recompute the centroid of each cluster.
5: until The centroids don't change

## K-means Clustering - Details

- Initial centroids are often chosen randomly.
- Clusters produced vary from one run to another.
- The centroid is (typically) the mean of the points in the cluster.
- 'Closeness' is measured by Euclidean distance, cosine similarity, correlation, etc.
- K-means will converge for common similarity measures mentioned above.
- Most of the convergence happens in the first few iterations.
- Often the stopping condition is changed to 'Until relatively few points change clusters'
- Complexity is $\mathrm{O}(\mathrm{n} * \mathrm{~K} * \mid$ *d)
- $\quad \mathrm{n}=$ number of points, $\mathrm{K}=$ number of clusters,

I = number of iterations, $d=$ number of attributes

## Evaluating K-means Clusters

- Most common measure is Sum of Squared Error (SSE)
- For each point, the error is the distance to the nearest cluster
- To get SSE, we square these errors and sum them.

$$
S S E=\sum_{i=1}^{K} \sum_{x \in C_{i}} \sum_{j=1}^{n}\left(m_{j}^{i}-x_{j}\right)^{2}
$$

- $x$ : a data point in cluster $C_{i}, x_{\mathrm{j}}$ is the jth attribute of $x$, and $\mathrm{m}_{\mathrm{j}}^{\mathrm{j}}$ is the jth attribute of the representative point for cluster $C_{i}$
- can show that $\mathrm{m}_{\mathrm{j}}$ corresponds to the center of the cluster
- Given two clusters, we can choose the one with the smallest error
- One easy way to reduce SSE is to increase K, the number of clusters
- A good clustering with smaller K can have a lower SSE than a poor clustering with higher K

## Two different K-means Clusterings

## I mportance of Choosing I nitial Centroids

Iteration 5

## Problems with Selecting I nitial Points

- If there are K 'real' clusters then the chance of selecting one centroid from each cluster is small.
- Chance is relatively small when K is large
- If clusters are the same size, $n$, then

$$
P=\frac{\text { number of ways to select one centroid from each cluster }}{\text { number of ways to select } K \text { centroids }}=\frac{K!n^{K}}{(K n)^{K}}=\frac{K!}{K^{K}}
$$

- For example, if $K=10$, then probability $=10!/ 10^{10}=0.00036$
- Sometimes the initial centroids will readjust themselves in 'right' way, and sometimes they don't
- Consider an example of five pairs of clusters

## 10 Clusters Example

Starting with two initial centroids in one cluster of each pair of clusters

## 10 Clusters Example

Iteration 1

Iteration 2

Starting with two initial centroids in one cluster of each pair of clusters

## 10 Clusters Example

Iteration 4

Starting with some pairs of clusters having three initial centroids, while other have only one.

## 10 Clusters Example

Starting with some pairs of clusters having three initial centroids, while other have only one.

## Solutions to I nitial Centroids Problem

- Multiple runs
- Helps, but probability is not on your side
- Sample and use hierarchical clustering to determine initial centroids
- Select more than k initial centroids and then select among these initial centroids
- Select most widely separated
- Postprocessing
- Bisecting K-means
- Not as susceptible to initialization issues

## Updating Centers I ncrementally

- In the basic K-means algorithm, centroids are updated after all points are assigned to a centroid
- An alternative is to update the centroids after each assignment (incremental approach)
- Each assignment updates zero or two centroids
- More expensive
- Introduces an order dependency
- Never get an empty cluster
- Can use "weights" to change the impact

## Pre-processing and Post-processing

- Pre-processing
- Normalize the data
- Eliminate outliers
- Post-processing
- Eliminate small clusters that may represent outliers
- Split 'loose' clusters, i.e., clusters with relatively high SSE
- Merge clusters that are 'close' and that have relatively low SSE
- Can use these steps during the clustering process
- ISODATA

## Limitations of K-means

- K-means has problems when clusters are of differing
- Sizes
- Densities
- Non-globular shapes
- K-means has problems when the data contains outliers.

## Limitations of K-means: Differing Sizes

Original Points

## Limitations of K-means: Non-globular Shapes

Original Points

K-means (2 Clusters)

## Overcoming K-means Limitations

Original Points
K-means Clusters

One solution is to use many clusters.
Find parts of clusters, but need to put together.
